Ced. Prof. Neurología: 6926514

Tijuana, Baja California, September 22, 2018.

To whom it May concern:

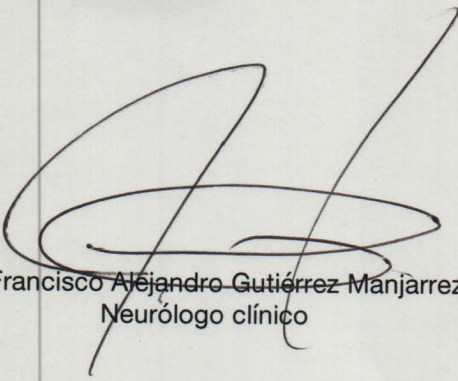

I have assessed the patient Jana Narendra, 33 years of age since June 2017, with diagnosis of multiple sclerosis, relapse remission.

It has presented sensory and motor symptoms, with magnetic resonances where it shows white matter lesions in the brain and cervical - dorsal spine, with study of visual evoked potentials of August 2018 with left optic neuritis.

Physical examination with vital signs within normal parameters, with right hyperreflexia, normal strength, without alterations in cerebellum, normal pupillary response.

Currently under treatment with Tecfidera 240 mg twice a day for 1 month.

It's important comment from current findings in the sequential MRI's (September 2017 - 2018) there is progressive atrophy and degeneration of the cervical spine which may indicate secondary progressive multiple sclerosis, which should be valued in later studies.
